

Figure 2 -- bill shape: the per-turn cost curve (C2: bought early, spent late)

A. absolute: cumulative model cost

B. normalised: where E2 and E3 are read

C. the confound first: environment actions per turn, failures in red (both published failure bands are in the caveat)

D. context growth: transcript or manual?

E4 IS THE BATTERY'S NUMBER, NOT THIS PLATE'S. Higher means context is accelerating: R2 of a quadratic fit to context tokens per turn, minus R2 of a linear one. It reads the token series, not the priced one, so it survives a change in the price list.

ABSENT, NOT ZERO -- 31 of 101 drawn runs
carry no E4:
8 run(s):
fewer than five turns; a quadratic needs room
23 run(s):
no battery run at all; battery v2 scores the arms
