

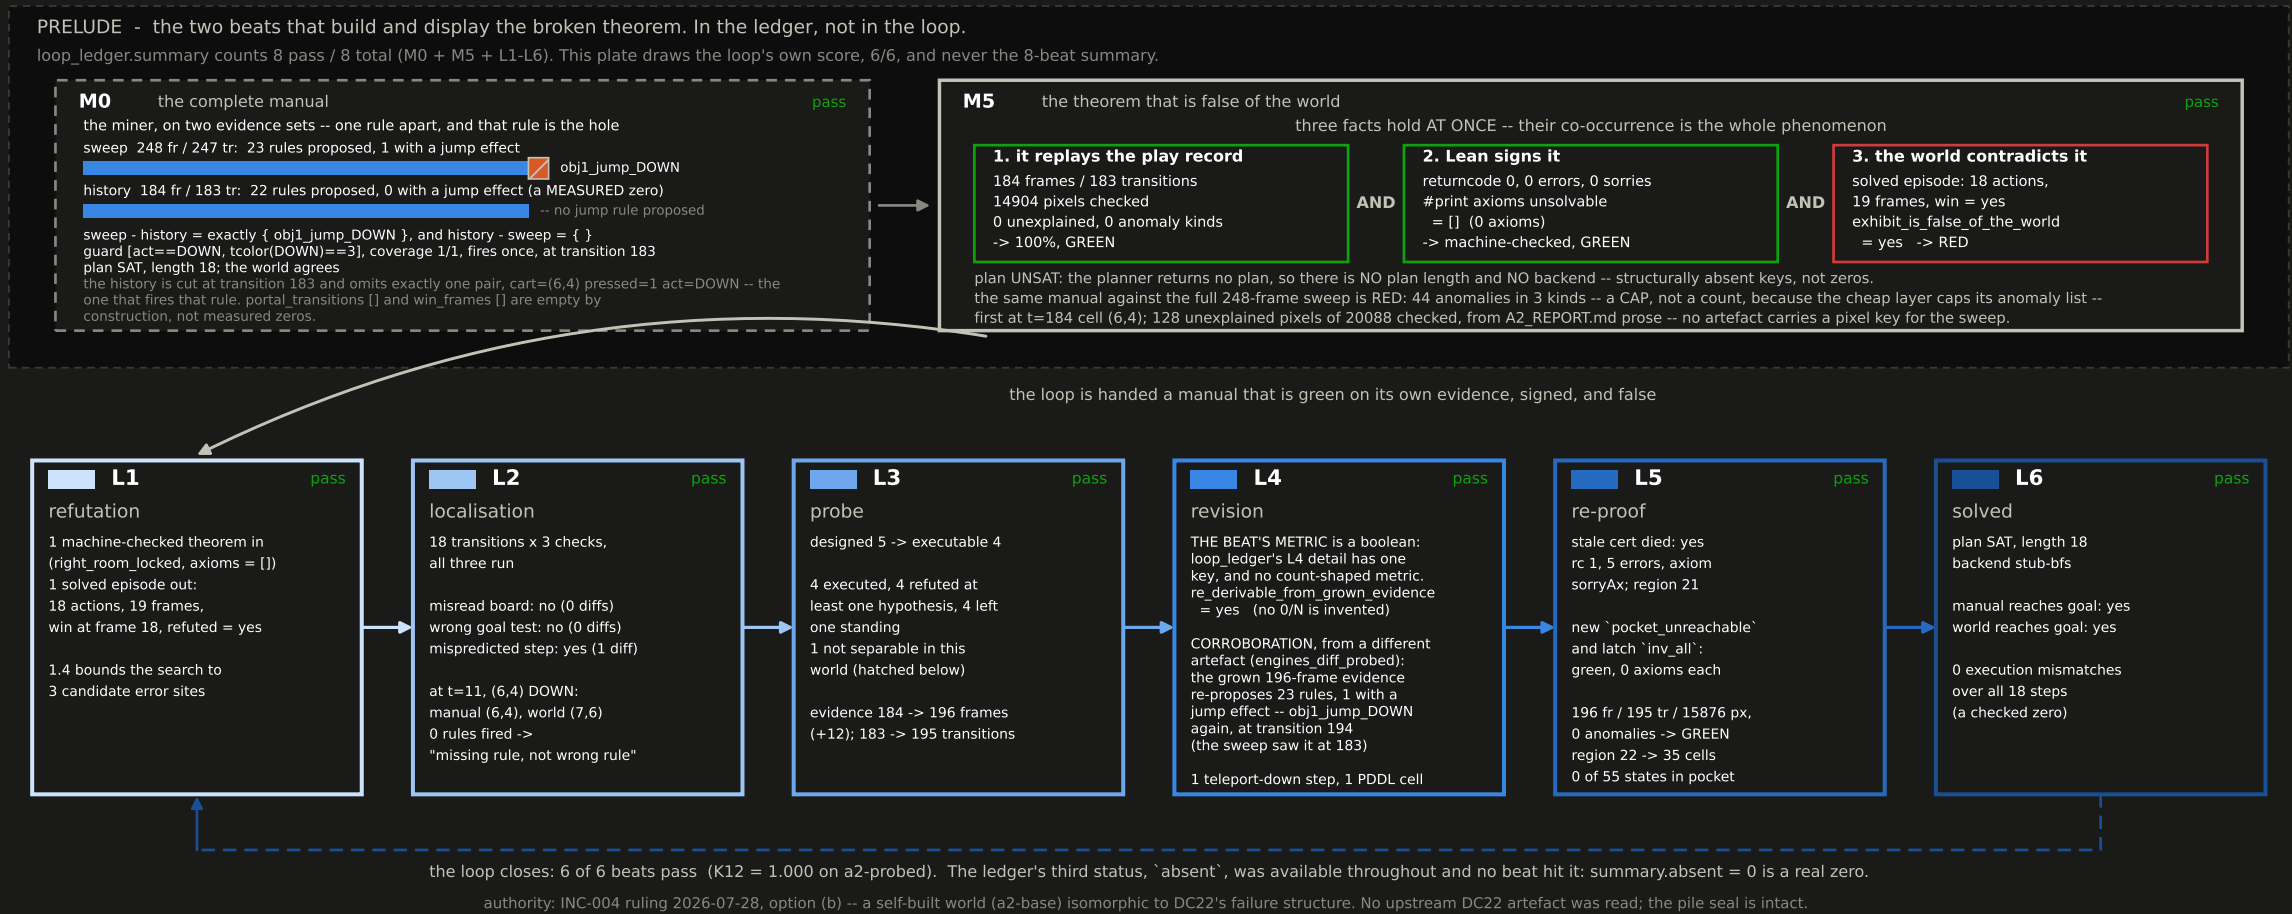

Figure 5 -- the DC22 case in cold-start-a2: a machine-checked theorem that is false of the world, and the six beats that repaired it

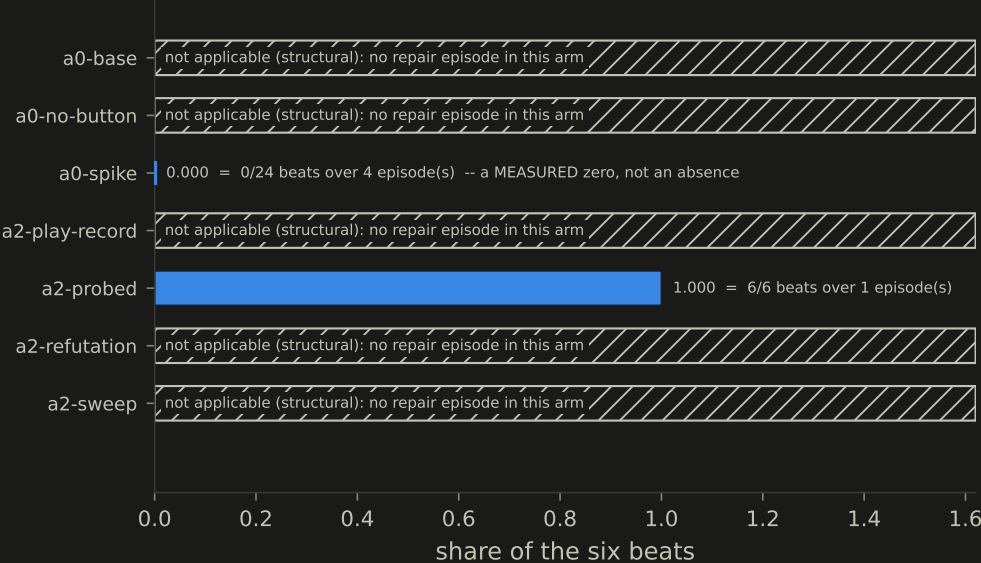

A. the six-beat repair loop L1-L6, and the two prelude beats that hand it a theorem that is proved, green, and false

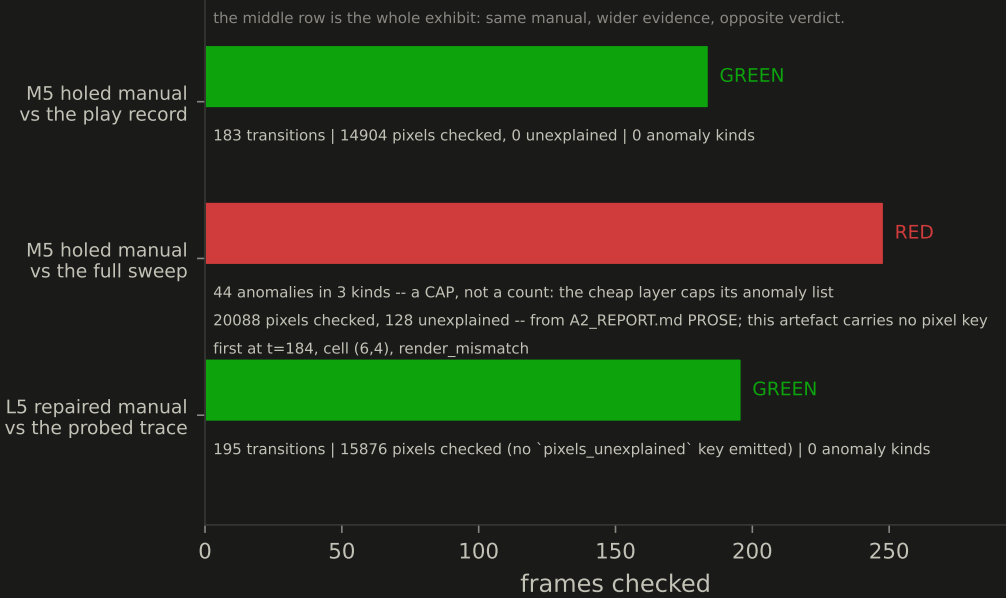

B. L3: 5 probes designed, 4 executable, 4 left a hypothesis standing, 1 not separable

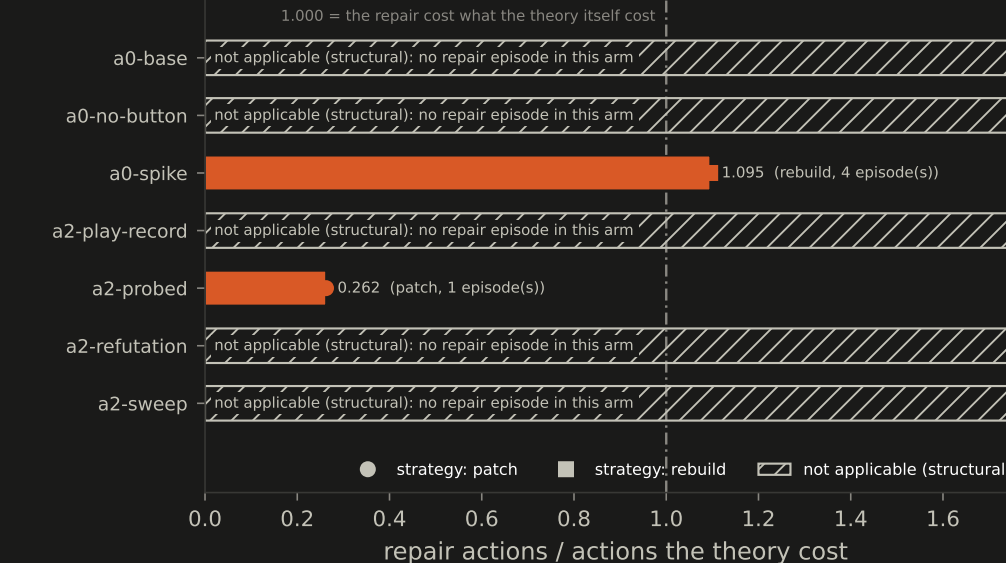

D. K12 -- repair beats closed (higher is better)

C. one certifier, three evidence sets

E. K13 -- repair cost (LOWER is better)

Read the beat count carefully: loop_ledger.json records EIGHT beats and summarises 8/8 pass; the repair loop is the SIX L-beats, and M0/M5 are prelude, drawn subordinate above. Panel B: 'probe_report.confirmed' is 0 only because a probe that refutes anything is coded 'refuted' -- all four executable probes left a hypothesis standing, so '4 refuted / 0 confirmed' would misread the file; P-03 is hatched because probes.jsonl carries no outcome fields for it at all, not because it scored nothing. Panel C: the full-sweep row's 44 is a CAP -- the cheap layer caps its anomaly LIST -- and that is unchanged by the pixel figures beside it, which count something else and come from A2_REPORT.md PROSE (20088 = 248 frames x 81 px, cross-checked; no artefact carries a pixel key for the sweep). M5's plan is UNSAT and therefore has no length and no backend -- structurally absent, never 0. L4's own ledger metric is a boolean with no count-shaped metric behind it, and none is invented: the rule counts on that node are corroboration from a different artefact, labelled as such. Panels D/E: five of the seven theory-bearing arms are 'not-applicable' by the battery's own reason (no repair episode) and are hatched; a0-spike's K12 = 0.000 is a MEASURED zero (0 of 24 beats over 4 rebuild episodes) and is labelled as one. Arm and world are perfectly confounded here: a2 and a0-spike are different self-built worlds, so K13's 0.262-vs-1.095 contrast is a strategy contrast inside that confound, not a controlled one.
